How much energy does FCDI use?

Zhang et al. compared FCDI technology with reverse osmosis (RO) and electrodialysis (ED) technologies and discovered that FCDI technology requires 0.22-14 kWh/m<sup>3</sup> of energy consumption for the same water production and recovery rate, which is higher than RO technology (0.19-0.833 kWh/m<sup>3</sup>).

How does FCDI work?

Different from other electro-driven desalination devices that employ solid electrodes to remove target ions, FCDI applies flow-electrodes, normally carbon slurry, which can be recirculated during the desalination process, and thus greatly facilitates continuous desalination.

Can a three-chamber device recover energy from an FCDI?

As a result, increased average power densities were obtained, 46.7% and 8.4% higher than the control group, respectively. A previous research employed a three-chamber device to recover the energy from an FCDI [11].

Can a rechargeable battery be concentrated using a FCDI device?

In this study, we have investigated the energy recovery from the energy stored during FCDI desalination. Since flow electrodes continuously circulate the FCDI cells and remove the sodium-chloride ions from the feed saline water, the effluent is continuously desalinated ...

The world is set to add as much renewable power over 2022-2027 as it did in the past 20, according to the International Energy Agency. This is making energy storage increasingly important, as renewable energy cannot provide steady and interrupted flows of electricity. Here are four innovative ways we can store renewable energy without batteries.

NOTE: This blog was originally published in April 2023, it was updated in August 2024 to reflect the latest information. Even the most ardent solar evangelists can agree on one limitation solar panels have: they only produce electricity when the sun is shining. But, peak energy use tends to come in the evenings, coinciding with decreased solar generation and causing a supply and ...

Results obtained show that the integrated FCDI/MF system can be used to successfully separate brackish water (of salinities 1, 2 and 5 g L<sup>-1</sup>) into both a potable stream (<0.5 g L<sup>-1</sup>) and a brine stream (concentrated 2-20 times) in a continuous manner with extremely high water recovery rates (up to 97%) and reasonable energy consumption.

Consequently, if sufficient active membrane area is installed, the FCDI can be more energy efficient than BWRO for obtaining the same water quality. As shown in Fig. 10 a, the SAC was calculated for 120-h batch-mode operation and reached a steady state after 30 h, achieving the maximum SAC (mSAC) of 0.26 mg/g. However, because FCDI uses a flow ...
