In physics, energy density is the quotient between the amount of energy stored in a given system or contained in a given region of space and the volume of the system or region considered. Often only the useful or extractable energy is measured. It is sometimes confused with stored energy per unit mass, which is called specific energy or gravimetric energy density.

When current is applied, the current-bearing elements of the structure exert forces on each other. Since these elements are not normally free to move, we may interpret this force as potential energy stored in the magnetic field associated with the current (Section 7.12). We now want to know how much energy is stored in this field.

Thermal energy storage usually consists of two components: a storage element and a heat transfer system. During the energy storage process, thermal energy is supplied to the storage from a heat source such as solar panels or biomass boilers. This energy is then stored in a high heat capacity material that absorbs heat and keeps it constant.
